Hey Guys,

Here is an aerial picture of a field of ours that was treated for a severe aphid infestation with Mustang Max, soon after treatment the dry weather set in and the spray evidently extended the life of the treated plants. The buffer/test strip area to the right died out at least a week earlier as well as missed the benefit from the late rains.

There was an 11bu/ac yield difference as you can see from the test plot data. It was sprayed around the 8th of August and had 500 or more on each leaf plus covered on the pods and stems, as I mentioned a severe infestation, hope the info is useful.

Justin Miller

PS You can see the FIRST plot in the upper corner of the picture as it was also treated.
